- ◀ People spend >70% time indoor
- ◀ Ensure safety and comfort of occupants in terms of IAQ
- ◀ How?

◀ Assessment of indoor air quality (IAQ)

→ understanding the level of occupant exposure to various air pollutants

→ formulating indoor environmental control strategies

◀ Test concentration $\Phi_{\theta} \leq$ set limit Φ^* → **acceptable**

◀ Test concentration $\Phi_{\theta} >$ set limit Φ^* → **unacceptable**

◆ Long-term and comprehensive measurement?

◆**cost, time**

◆ → by some sampling scheme

◆**measurement errors?**

- To what level we should believe in the assessment
- How to interpret test results for acceptance

Epistemic approach

uncertainties

Epistemic IAQ Assessment

space is unacceptable

Tested unacceptable given an 'unacceptable' environment

probability of having an 'unacceptable' environment

$$P(A | B) = \frac{P(A)P(B | A)}{P(B)}$$

Tested unacceptable

The diagram illustrates the components of the probability equation. Two yellow arrows point from the text 'space is unacceptable' and 'Tested unacceptable given an 'unacceptable' environment' to the numerator $P(A)P(B | A)$. A third yellow arrow points from the text 'Tested unacceptable' to the denominator $P(B)$.

Event A: Space is unacceptable

Event B: Tested unacceptable

Epistemic IAQ Assessment

(“Prior” knowledge)
space is unacceptable

(Uncertainties of sampling scheme)
Tested unacceptable given an
'unacceptable' environment

probability of having an
'unacceptable' environment

$$P(A | B) = \frac{P(A)P(B | A)}{P(B)}$$

Tested unacceptable

The diagram illustrates the components of the epistemic IAQ assessment. It features a central equation: $P(A | B) = \frac{P(A)P(B | A)}{P(B)}$. Three yellow arrows point towards this equation. One arrow points from the text "(“Prior” knowledge) space is unacceptable" to the $P(A)$ term. Another arrow points from the text "(Uncertainties of sampling scheme) Tested unacceptable given an 'unacceptable' environment" to the $P(B | A)$ term. A third arrow points from the text "Tested unacceptable" to the $P(B)$ term. To the left of the equation, the text "probability of having an 'unacceptable' environment" is written.

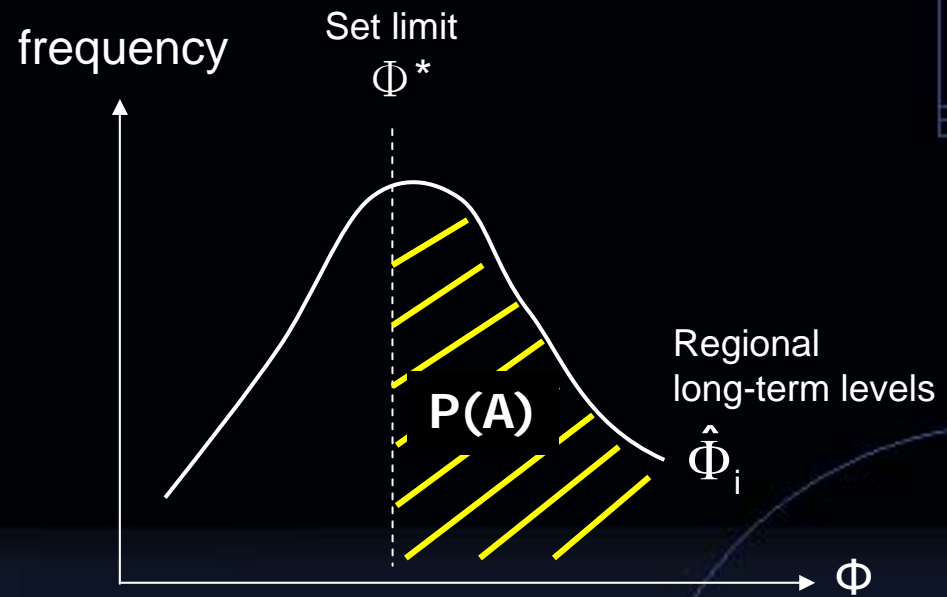

Event A: Space is unacceptable

Event B: Tested unacceptable

Prior knowledge of office IAQ

$$P(A) = 1 - \int_{-\infty}^{\Phi^*} \hat{\Phi}_i d\Phi_i$$

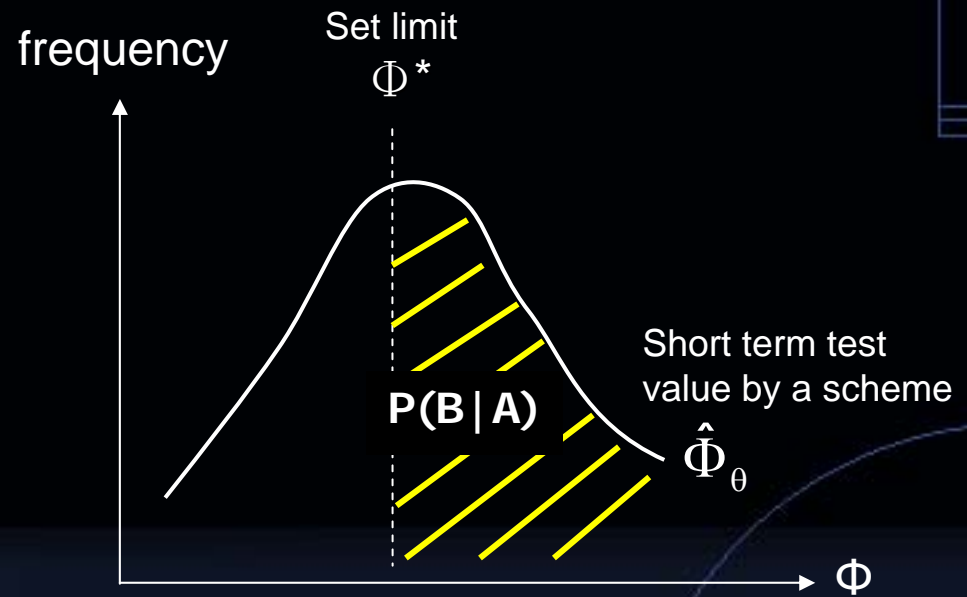

Regional levels of similar offices would be used to formulate “prior” knowledge of failure

Uncertainties of sampling schemes

$$P(B | A) = 1 - \int_{-\infty}^{\Phi^*} \hat{\Phi}_\theta \, d\Phi_\theta$$

Probable short term tested levels by a scheme

Example for demonstration

- ▶ CO₂
- ▶ relationships between indoor CO₂ concentration and IAQ:
- ▶ the health effects of elevated CO₂ concentrations,
- ▶ the impact on occupant perceptions of the environment,
- ▶ the relationship with other contaminants,
- ▶ outdoor air ventilation rate

Field measurements (1)

- ↖ Application of the epistemic approach to CO₂ level assessment
- ↖ A district survey was carried out in 330 offices
- ↖ Samples were randomly selected and covered all major commercial regions of office development in Hong Kong
- ↖ For determining the prior failure rates of workplace IAQ in this region
- ↖ CO₂ levels were measured in the occupied zones during office hours

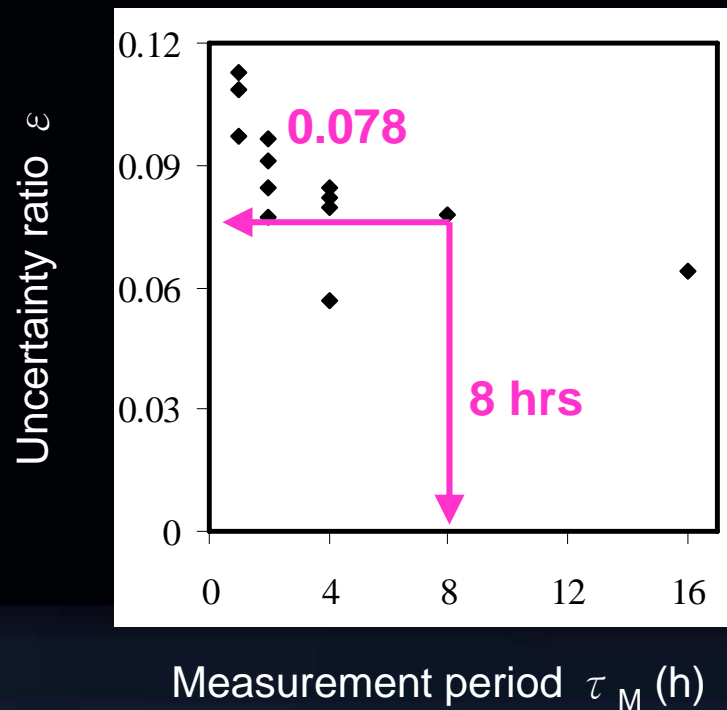

Results

- ▶ geometric mean $\mu_N = 639$ ppm
- ▶ set limit Φ^* from HKEPD
 - <800 ppm → Excellent
 - <1000 ppm → Good
- ▶ only a small number of offices exceeded the two criterion limits set for offices in Hong Kong,
 - $P(A)_{\Omega}^{\Phi^*=800} = 1 - 0.83 = 0.17$ ($CI_{95} = 0.13-0.20$)
 - $P(A)_{\Omega}^{\Phi^*=1000} = 1 - 0.97 = 0.03$ ($CI_{95} = 0.01-0.04$).

Field measurements (2)

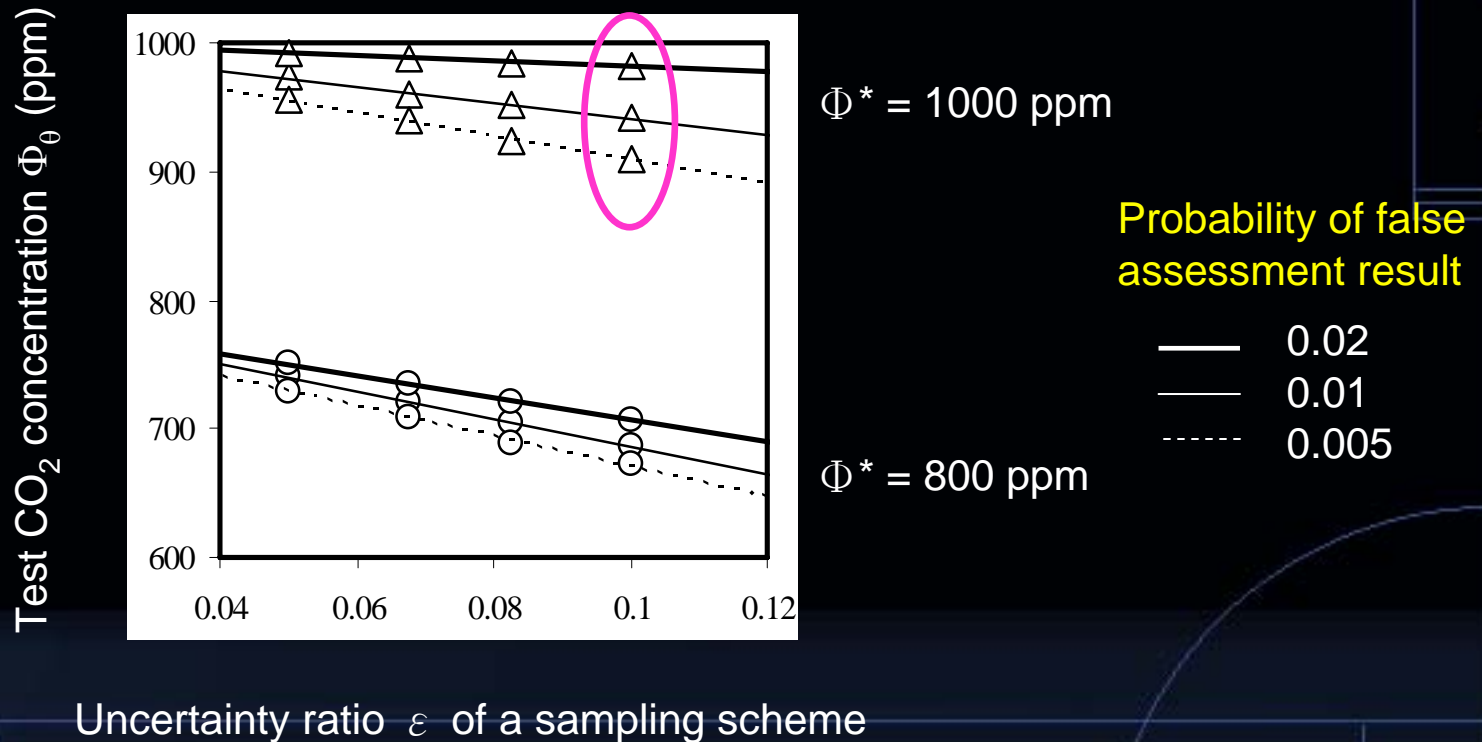

- ◆ To quantify the probable errors associated with some sampling schemes, a one-year CO₂ measurement was also conducted in an in-use office building
- ◆ open-plan offices
- ◆ an independent air handling unit (AHU) for each office floor
- ◆ supply 20% fresh air and 80% re-circulated air mix.
- ◆ CO₂ concentrations were measured at a number of comparable spatial locations on one open-plan office floor
- ◆ in the occupied period on all working days for one year

Uncertainties of some sampling schemes over a measurement period

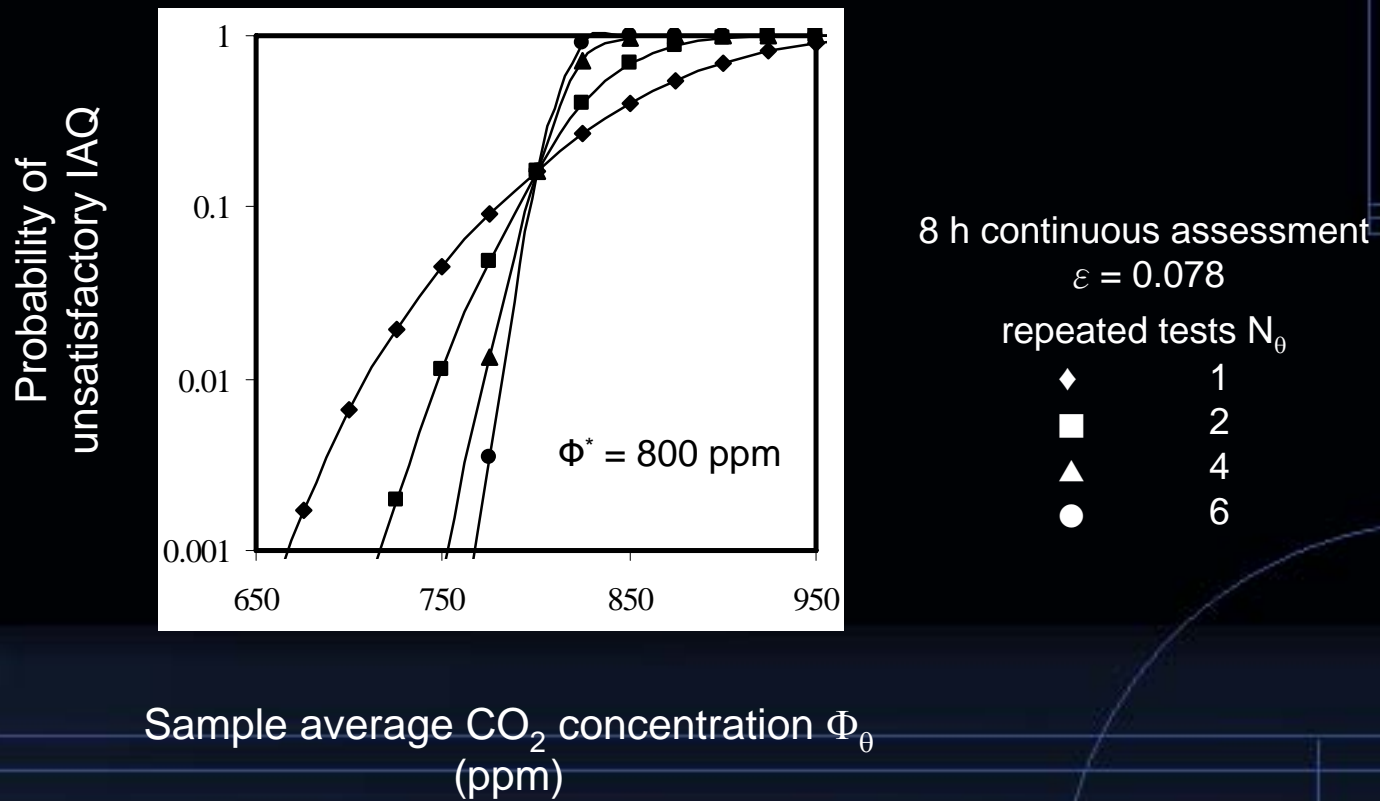

$$\varepsilon = \sigma_{\theta} / \mu_{\theta}$$

Maximum test values Φ_θ for satisfactory IAQ at indoor CO_2 level Φ^*

Probability of unsatisfactory IAQ against test CO₂ concentration Φ_θ for an office in Hong Kong

Conclusion

- ◆ Long-term measurement could be the best channel to identify indoor air pollution mitigation needs, but it usually requires considerable measurement efforts to attain accurate results.
- ◆ Preliminary IAQ assessment for offices in Hong Kong was thus proposed.
- ◆ To avoid overreliance on the assessment results, measurement uncertainty must be considered as well.
- ◆ This study proposed that regional survey results of IAQ could be treated as a prior understanding in an epistemic approach to assessing the acceptance of an indoor environment in the region.

Conclusion

- ◆ CO₂, a common pollutant found in air-conditioned offices, was used as an example to demonstrate the application of the epistemic IAQ assessment method.
- ◆ The prior failure rates of offices were determined from a large scale regional survey of 330 air-conditioned offices in Hong Kong.
- ◆ Taking the sampling uncertainty into account, the acceptance of office IAQ was evaluated based on a test CO₂ level against an action CO₂ level.
- ◆ With an 'agreed' range of acceptable assessment uncertainties, different parties involved in IAQ monitoring can make better decisions to devise the appropriate and cost-effective sampling strategies for IAQ control and improvement.
